The XSL stylesheet is looking for elements in the XML document with the identity of "aasa_user.user" which do not exist. They have the name "user" instead. I cannot understand why this is happening.

If you look in file include.xml.php4.inc you will see in function addData2XMLdoc() a call to $dbobject->getClassName() which provides the element identity for writing data from that object out to the XL document. The getClassName() function exists within file std.table.class.inc.

Can you step through with your debugger and see what is happening at that point?
