Why do you think that a record with a null parent\_id is not normalised? It signifies that a node does not have a parent, which either means that it is at the top of the tree, or it has been orphaned (ie: waiting to be assigned to a parent).

My tree structure is not supposed to be the only way to represent a tree, it just happens to be the one that suited my purposes many years ago when a particular requirement arose. There may be other ways to handle tree structures, so you are free to implement whatever takes your fancy.
