PostgreSQL is peculiar because it has the hierarchy server->database->schema->table instead of server->database->table. When the framework code connects to a server it is possible to change the default database (or "schema" in postgres) to whatever you choose, or even to construct a query which accesses tables in more than one database (or "schema" in postgres). For this reason when using postgres the "database" name **MUST** be hard coded in the config file, and it is only the "schema" name which is dynamic. Please refer to <http://www.tonymarston.net/php-mysql/postgresql.html#database.connection> for details.
