I noticed that when you add a new entry to the $fieldarray of function _cm_changeConfig in any class, like for example: function _cm_changeConfig ($where, $fieldarray)
```
    {
     if (!isset($fieldarray['abc'])) $fieldarray['abc'] = 'anything';
     return $fieldarray;
    } // _cm_changeConfig
```
You will find that any operation on multiple records (eg. multiple selected records with enq1 or upd1, etc) of this object won't show the scroll bar. A work around is by moving the "add entry to $fieldarray" code to another function, for example _cm_getExtraData, which does not conflict with the scroll bar.

The _cm_changeConfig() method is supposed to be used only to change the configuration of that entity, such as the contents of the $fieldspec array. Adding extra values to $fieldarray should be done in the _cm_getExtraData() method.

It is possible to add extra values in the _cm_changeConfig() method, but as it is called several times a change to the contents of $fieldarray can have different results. The first time it is called in an UPD or ENQ task is before the call to getData(), so the $where string is not empty and $fieldarray shows the primary key of the first selection. If you make a change to $fieldarray at this point this will then replace the contents of the $where string, thus replacing the multiple selection with a single selection which causes the scroll bar to be removed as there are no other selections. When _cm_changeConfig() is called after getData() the $where string will be empty and $fieldarray will show the complete contents of the current record. Any changes you make to $fieldarray at this point will not affect the scroll bars.

If you wrap your code in the following condition it will work in the _cm_changeConfig() method:

```
if (empty($where) AND !empty($fieldarray)) {
    if (!isset($fieldarray['abc'])) $fieldarray['abc'] = 'anything';
} // if
```

I understand now. Thank you.
