One way I know of to have both online and offline versions of the same application is to use XFORMS, but I have never used this technology so am I unable to advise you on how to go about it.

An easy alternative would be to put a copy of Apache/PHP/MySQL on each laptop, with the appropriate databases. All you then have to worry about is synchronising the databases to keep them in step. One method of copying from a laptop to the central server may be to use the contents of the AUDIT database.
