Subject: Workflow implementation question

I have a simple task that adds a new record (add1). On some occasions the data for one particular field will not be known to the user entering the data.

What I would like to do via the workflow is to put an entry on the Workitems list for a user to update the data missing in the recently added record. However, if the particular data had been entered when the record was added, for there to be no record added to the workitems list.

I have tried several ways to achieve this but with no success. It seems that I need to have another transition between my add task (and start place) and the update transition. I would attach my guard statements to this extra transition. One leg would go to the update task and one would go to the end.

Is this a possible way to resolve this issue? What should my extra transition do? Am I going about this in completely the wrong way please can you suggest a better way forward.

With regards

Graham Jones
