Ok, setting `$GLOBALS['http_server'] = ''`; and `$GLOBALS['https_server'] = 'secure.ivado.com'`; fixed the problem (`http_server` is blank because this server ONLY hosts `https://secure.ivado.com`).

Which in itself poses another problem, as many links within the application want to navigate to an "http" link, which on this particular server doesn't exist. This server ONLY hosts `https://secure.ivado.com`

Is there any way to get around this?

Also, I had to drop and recreate the 'audit' table (certain permission errors, etc., very weird). After doing so, however, I cannot login with mgr/password (I'm giving a "Security Violation" error).

Sorry for all of the problems. Having a heck of time getting this to install, but I really think it'll be worth it.

Mik
