One more question: I want to examine if the the selected file can be deleted. I try to do this in the _cm_pre_DeleteRecord($rowdata) function with the code below.
I will do this with the _cm_getExtraData method. But $data shows only the occurences in the 'virtual' table 'training_plan_uebungen_pic_file' where all the pics are listed. Why I don't get back the occurences of 'training_plan_uebungen'. Isn't the $dbobject linked to 'training_plan_uebungen'?

```
class training_plan_uebungen_pic_file extends Default_Table
{ .....

    function _cm_pre_deleteRecord ($rowdata)
    // perform custom processing before database record is deleted.
    // if anything is placed in $this->errors the deletion will be terminated.
    {
        // this entry exists in the file system, not the database
        $filename = $this->picker_subdir .'/' .$rowdata['file'];

        // htManager changes
        // check if pic belongs to the appropriate account or is related to an exercise in
'training_plan_uebungen'
        $prefix_pattern = prefixAccount($_SESSION['rdcaccount_id']);

        // get contents of table 'training_plan_uebungen'
->        $dbobject =& RDCsingleton::getInstance('training_plan_uebungen');
 $fieldarray['training_plan_uebung_pfad_grafik'] = $filename;

 $data = $dbobject->_cm_getExtraData($where, $fieldarray);

        // only files with appropriate rdcaccount_id can be deleted
        if (preg_match('/^'.$prefix_pattern.'/i', $rowdata['file']) and count($data) == 0)
        {
         $result = unlink($filename);

        }

        return $rowdata;

    } // _cm_pre_deleteRecord
```
