I notice that your link table contains two rdcaccount_id columns, one for each of the parent tables. Unless the rdcaccount_id column is part of the primary key in those parent tables it is not necessary to define them as foreign keys in the link table. The way that a POPUP2 works is that you first identify a single row on the parent/outer table, then use the primary key as the WHERE clause when reading from the child/inner table. If you are reading entries from the child table which do not belong to the parent then there is something wrong.
