No. You will need to modify each database table to include a field which identifies who can access that record, then have some mechanism to compare this field with the user_id (or user group or whatever) to find out if a particular user can access a particular record. Or if a user can view a record but not update or delete it.

Each case is quite unique, with different requirements, so it would be quite difficult to have something built into the framework to do it automatically. There are just too many possible variations.
