There is no significance to the fact that in

<http://www.tonymarston.net/php-mysql/radicore-tutorial4.html#figure4> I chose `x_tree_node_snr` (subclass) and `x_tree_node_jnr` (subclass). Either one could have been `x_tree_node` (superclass). The only point is that the two tables must have different names so that the system can work out which data goes where.

If you look at <http://www.tonymarston.net/php-mysql/radicore-tutorial4.html#relationships.step2> you will see where the `_cm_popupCall()` method in `x_tree_node_jnr` is modified to pass the current value in `$where` automatically to the popup2 screen. The default is to pass nothing.

There are two choices for providing a primary key value for the outer entity in a popup2 form - if the value is available before you call the popup then use the `_cm_popupCall()` method, if it is not then you must call a separate popup1 form after the popup2 has been activated. That is explained in the FAQ.
