Hi,

I'm accessing some existing PostgreSQL databases on macos. Most of these have a primary key "id" whereas the foreign key is usually `object_id`; I know that it is preferred using the same name, but that's no option. Luckily `include.library.inc` contains a function `convert_parent_id_to_child_id()` to handle this particular case.

The function is called in `std.table.class.inc`, in the `getData()` function (line 2551 in the last version).

However for this to work properly the call to `where2array($where, $this->pageno, false)` a few lines higher should be called with the last parameter set to true.

Regards,

Patrick
