I just wanted to tell you that I found a way which fits my needs best. I expanded my parent table structure with the key fields with the prefix lup for lookup. In these fields I store the parent occurence via a popup. In my list2 pattern I can now call an add5 pattern to show all the child occurences from this record.
Normally a team is defined for one saison/period and consists of about 20 persons. And normally the team in the subsequent saison has about 80% of the team members from last year. In this way I can insert all team members and delete the members who have left the team. This is quite comfortable for me.
If I use a link1 pattern I have to scroll through all possible (100 til 200 or even more) team members. This takes too much time for me. This was just to give you a feedback.
