The `getData()` method, and therefore the `_cm_pre_getData()` method, is called each time a web page is built. Once a page has been loaded for the first time and the `_cm_pre_getData()` method called for the first time, any activities you perform in that page, whether it be pressing a hyperlink or pressing a button, which cause that page to be refreshed will result in repeated calls to `getData()`. This means that after you have constructed the various SQL component strings the first time you must not allow subsequent calls to `_cm_pre_getData()` to corrupt those strings.
