The convention here is that all primary keys are named 'id' (1 pk per table) and all foreign keys are named <tablename>\_id.

Unless I'm missing something this convention looks to create a lot of extra work for me. In particular in the list2 transactions.

e.g. if I have the following tables: group, group\_employee, and employee where group\_employee is the link table between group and employee. when I want to do a list2 employees of a particular group I have to modify the where clause in the \_cm\_pre\_getData function and change 'id' to 'group\_id'. Then it doesn't look like I can display groups of a particular employee because how do I know to change 'id' to 'employee\_id' or 'group\_id'?

So, My question: Is this convention going to cause me too many problems or did I miss something?

p.s. Changing the convention is not a problem- so if you recommend that let me know.  
thanks

I avoid conventions like this because they cause more problems than they solve, just like the problem you have just encountered. See <http://www.tonymarston.net/php-mysql/technicalkeys.html#worse1> for a more detailed explanation of this problem.

Your problem is that the WHERE clause passed down from the parent form contains "id='something'" but the column name 'id' has to be translated into either 'employee\_id' or 'group\_id' depending on the parent form. It would be possible to obtain the name of the previous form using either the getPreviousScript() or getPreviousTask() functions, but I would strongly recommend dropping that convention and change the primary key for each table so that instead of 'id' you have '<tablename>\_id' instead. This will cause fewer problems in the long run.
